NAME
cloudprint-service – manage the Google Cloud Print proxy

SYNOPSIS
systemctl *start* **cloudprintd.service**

> Start the **cloudprintd** service. This will fail if the credentials have not been established. The service will normally start automatically when the computer is running.

systemctl *stop* **cloudprintd.service**

> Stop the **cloudprintd** service. Login credentials are not lost. Normally, the printer will continue to be shown as a valid destination. Any jobs spooled during that time will print when the service is restarted.

systemctl *status* **cloudprintd.service**

> Determine whether the service is running or not.

DESCRIPTION
The **cloudprintd** services manages the operation of a Google Cloud Print proxy. It makes locally-defined CUPS printers available for use by approved Google users, both locally and remotely.

It is recommended that a dedicated account be used for this service. Printers can be shared from that account to others via the printer management page at *https://www.google.com/cloudprint?#printers*

Authentication credentials can be established using the wrapper script **cps-auth**.

FILES
/etc/default/cloudprintd

> This file contains a number of parameters that control cloudprint. View the file for more details.
